- Paper
- Primary Outcomes
- Secondary Outcomes
- Reported Result
 - $\circ\,$ "When compared with AC alone, CDT had lower mortality but high major bleeding and numerically higher ICH"
 - \circ "The risk of morality and ICH was high with ST when compared with CDT.
 - $\circ\,$ Findings were similar when analysis was restricted to intermediate risk PE.

Problems

The Definition of Risk Groups is not Stated

- Uses "intermediate risk," "high risk", and "intermediate-high risk," thus mixing terminologies
 - 2019 ESC: low, intermediate-low, intermediate-high, high
 - $\circ~\textbf{2011}$ AHA: massive, sub-massive, low risk
 - 2016 CHEST: low high, PE without hypotension, PE with hypotension

Very few RCT patients got CDT

Total	Papers	(n=45)
- v cui	i apeis	(11-45)

patient_type	number	percent	
AC	19976	24.4%	
CDT	9610	11.8%	
ST	52119	63.8%	
total	81705	NA	

Intermediate-Risk Papers (n=20)

patienttype^number^percent^ |AC|8873|75.9%| |CDT|1929|16.5%| |ST|883|7.5%| |total|11685|14.3% (of \$n{total}\$)

RCT Trials Only (n=17)

patient*type^number^percent*^ |AC|1101|49.8%| |CDT|78|3.5%| |ST|1031|46.7%| |*total*|2210|2.7% (of \$n{total}\$)

This means that the number of CDT patients from RCTs is only \$\frac{n{CDT}}{n{total}}=\frac{78}{81611}=0.096\%\$ of the study total!!

The Primary Outcome is not reported correctly

The paper utilized a network meta-analysis (1,2,3).

They list that "[t]he primary analysis compared CDT and systemic fibrinolysis with AC alone." However, they report the CDT vs AC and ST vs AC outcomes, not the network of all three.
